

19. Deployment

WhereScape generates deployment packages to deploy objects and code to different metadata repositories (Development, Test, UAT and Production). Deployments handle new objects, changed objects, dependencies and deletes. Deployments can be deployed via command line (e.g. via GIT/Azure DevOps) or from within the WhereScape application.

Define the deployment name and version

Build Deployment Application

This process builds the files necessary to allow the deployment of a data warehouse solution. These files are read and processed by the Setup Administrator utility. Specify the application identification details and then select the objects to be deployed to and/or deleted from another repository.

Output Directory:

Application Identifier: Application Version:

Application Name:

Description:

You can select or enter a previous application file as a starting point for this application.

Previous Application:

Pre Application Load SQL (the following optional SQL statement will be issued before the application load commences):

Post Application Load SQL (the following optional SQL statement will be issued after the application load completes):

Select the Objects to deploy

Objects can be manually selected, project driven or driven from a track-back / track-forward diagram.

Build Deployment Application

Select Objects to Add or Replace in the Destination Repository. Inactive groups/projects are not shown. In order to see them, you need to use maintenance screen.
